#### Abstract

Elastic scattering of positive and/or negative pions ( $\pi^{+}$and/or $\pi^{-}$) by nuclei has been studied by means of Glauber's multiple scattering theory (GMST). The differential, total and total elastic cross sections using both the full series expansion and the first order correction (called optical limit results, OLA) of the Glauber amplitude, have been calculated. The in-medium $\pi N$ amplitude ( $\sigma_{e f f .}, \sigma_{e f f .}$ ) as well as the free $\pi N$ one ( $\sigma_{\text {free }}$, $\left.\sigma_{\text {free }}\right)$ are invoked into the full series calculations of the Glauber amplitude and our results were compared with the corresponding experimental data. These calculations are carried out for the elastic collisions, $\pi^{-}-{ }_{2} \mathrm{He}^{4}$ at incident energy $180 \mathrm{MeV}, \pi^{ \pm}-{ }_{3} \mathrm{Li}^{6}$ at $240 \mathrm{MeV}, \pi^{-}-{ }_{6} \mathrm{C}^{12}$ at incident energies 180,200 and 260 MeV , $\pi^{+}-$ ${ }_{8} \mathrm{O}^{16}$ at 240 and 270 MeV and $\pi^{ \pm}-{ }_{20} \mathrm{Ca}^{40}$ at energy 292.5 MeV . The comparisons reflect that, except around the minima, the full series calculations with the in-medium $\pi N$ amplitude are better in describing the scattering data than those using the free $\pi N$ one and both are better than the optical limit results.

Keywords: Glauber's multiple scattering theory; Differential cross section; Total cross section; Total elastic cross section; In-medium $\pi N$ amplitude.

## I. INTRODUCTION

The interaction of pions with nuclei has been actively studied for about twenty years [1-4]. The main focus of this effort to date has been to work at energies at or below the pion production threshold, which occurs for the pion-nucleon $(\pi N)$ interaction at $\pi$ kinetic energies of $\sim 175 \mathrm{MeV}$. At these energies, the basic $\pi N$ interaction is completely elastic which is under discussion here. The elastic interaction of pions with finite nuclei and with nuclear matter is of considerable theoretical interest for a number of reasons [5]. We are dealing here with one of the few examples of multiple scattering by a nucleus of an elementary particle projectile, the main other example of which is provided by the nucleon-nucleus interaction. Even as a more repetition of the latter with a different interaction, the $\pi$ nuclear multiple scattering would therefore be of interest. In particular, the $\pi$ nuclear interaction is, however, of such a qualitatively different structure compared to the nucleon one, that it must be considered to be of interest in its own right. Also, its connection to the basic processes is clearer and more immediate than in the case of nucleons. Moreover, the absence of poles in the low energy $(\pi N)$ scattering as well as the short range of the $(\pi N)$ interaction opens the possibility of establishing a very transparent connection between the elementary scattering and the $\pi N$ scattering, a connection which unfortunately is not so direct in the case of nucleons. The small recoil corrections in the pion case and the absence of a pion spin are also technical advantages compared to nucleons.

A great deal of low energy pion-nucleus elastic scattering data has been accumulated [6-12]. For the most part, the data were obtained for positive pions scattering from nuclear targets spanning a wide range of the periodic table in order to map out general features of elastic scattering. These experiments indicate that in the low energy region, the pion mean free path is long and pions penetrate to the nuclear interior [13].

Various authors have investigated pion-nucleus scattering for the purpose of studying nuclear structure and the pionnucleon interaction inside the nucleus [14, 15]. The main purpose of such investigations is to understand the mean field encountered by the pion while traversing the target nucleus. This field is usually described in terms of either multiple scattering processes which depend upon the nuclear charge distributions [16-25] or the complex optical model (OM) potential [26-30]. We will restrict ourselves here to the first one where the projectile undergoes multiple scatterings during its passage through the nucleus. Two independent multiple scattering theories have been used to describe the pion elastic scatterings from nuclei. The first is called Watson's multiple scattering theory (WMST) [31-33], the second is the well known Glauber's multiple scattering theory (GMST) [17-23, 34, 35], which is under discussion here. The theory is based on high-energy Eikonal approximation, in which the interacting particles are almost frozen in their instantaneous positions during the passage of the projectile through the target and the trajectory is nearly straightforward. However, because the Glauber theory is principally derived for the higher energy and the small-angle situations, the reliability of its results may be questioned in the case of low energy and large angle. The GMST has the great advantage of leading to straightforward calculations of the elastic pion-nucleus scattering crosssections from knowledge of free pion-nucleon scattering amplitude and nuclear densities.

The preliminary applications of GMST were found to have great successes in reproducing the hadron-nucleus scattering data [36-44]. The confidence in this theory encouraged the extension of its application to nucleus-nucleus collisions [4557].

Following the same procedures as that utilized in our previous works $[58,59]$ which takes into account the hadron as a projectile, we have studied in our present paper the elastic scattering of positive and/or negative pions ( $\pi^{+}$and/or $\pi^{-}$) by different nuclei, like, ${ }_{2} \mathrm{He}^{4},{ }_{3} \mathrm{Li}^{6},{ }_{6} \mathrm{C}^{12},{ }_{8} \mathrm{O}^{16}$ and ${ }_{20} \mathrm{Ca}^{40}$ at intermediate energies. We considered here both the full series
expansion and the first order correction of the Glauber amplitude.

Correlations within the nucleus are of fundamental theoretical interest but unfortunately they are difficult to study experimentally. In pion-nucleus scattering they manifest themselves through a change of the effective pion-nucleon cross section via the so called in-medium $\pi N$ amplitude [60-64]. Goldberger [65] suggested that the effective total nucleonnucleon cross section $\sigma_{\text {eff }}^{(1)}$ of a bound nucleon is less than that of free nucleon because the Paula principle forbids momentum transfer, to a bound nucleon, less than a minimum value sufficient to bring it outside the Fermi sea [66]. The relation between $\sigma_{e f f}^{(1)}$ and $\sigma$ as quoted by Goldberger is given by $\sigma_{\text {eff }}^{(1)}=\sigma\left(1-\frac{7 E_{F}}{5 E}\right)$ where $E_{F}=38.4 \mathrm{MeV}$ which corresponds to Fermi momentum $K_{F}=1.38 \mathrm{fm}^{-1}$ and E is the kinetic energy of the incident nucleon. Abul-Magd et al. [67] considered that the effective NN scattering amplitude implies that $\sigma_{\text {eff }}^{(2)}+1=\alpha^{2}+1 /\left(1-\frac{7 E_{F}}{5 E}\right)$. However, Glauber [17] and Faldt et al. [68] argued that the effective nucleon-nucleon cross section $\sigma_{\text {eff }}^{(2)}$ should be larger than the free one. It was shown by Glauber that the Pauli correction imply an effective cross section $\sigma_{\text {eff }}^{(2)}=\sigma^{\prime}\left(1+x \sigma^{\prime}\right)[66,69]$. This relation is the golden rule that used in high-energy physics, $\sigma^{\prime}=\sigma(1-i \alpha)$ is the free pion-nucleon cross section including real and imaginary parts. The actual numerical value of $x$ is very much debated. As a guide one often uses the result of the Fermi-gas model [17] which gives $x \cong \frac{K_{F}^{2}}{10 \pi} \approx 0.06 \mathrm{fm}^{-2}$. It is helpful to study the effect of the in-medium correction on our results.

The present paper contains three more sections. Section II, contains the theoretical expressions used to calculate the differential, total and total elastic cross sections for the considered reactions. Section III includes the results and their discussions. The conclusion is given in section IV. The orbits, lengths and $\Delta$-matrices required for carrying out the calculations are exhibited in the appendix.

## II. THEORETICAL FRAMEWORK

This section is devoted to obtain the expressions for the differential $(d \sigma / d \Omega$ or $d \sigma / d t)$, total ( $\sigma_{T}$ ) and total elastic ( $\sigma_{e l}$ ) cross-sections for the elastic scattering of pion ( $\pi^{+}$and/or $\pi^{-}$) with light- and medium-weighted nuclei using Glauber's multiple scattering theory. These expressions are developed by using both the full series expansion of the Glauber amplitude and by taking into account the consistent treatment of the center-of-mass (c.m.) correlation.

In this theory, the elastic scattering amplitude between a pion of atomic number ' $Z_{\pi}$ " and a target nucleus of mass number " B " and atomic number " $\mathrm{Z}_{B}$ " is given as [48]

$$
\begin{equation*}
F_{\pi B}(\vec{q})=\frac{i k}{2 \pi} \Theta(\vec{q}) \int d \vec{b} \exp (i \vec{q} \cdot \vec{b})\left\{1-\exp \left(i \chi_{\pi B}(\vec{b})\right)\right\} \tag{1}
\end{equation*}
$$

where, $\vec{q}$ is the momentum transferred from the pion to the target nucleus $\mathrm{B}, \vec{k}$ is the incident momentum of the pion, and $\vec{b}$ is the impact parameter vector. $\Theta(\vec{q})$ is the center-of-mass correlation function [48]. $\chi_{\pi B}(\vec{b})$ is the phase-shift function resulting from the interaction of the pion with the target nucleus B.
By taking into account the Coulomb phase-shift function in addition to the nuclear one, we can write

$$
\begin{align*}
\chi_{\pi B}(\vec{b}) & =\chi_{n}(\vec{b})+\chi_{C}(\vec{b}) \\
& =\chi_{n}(\vec{b})+\chi_{C}^{p t}(\vec{b})+\chi_{C}^{E}(\vec{b}) \tag{2}
\end{align*}
$$

where $\chi_{C}^{p t}(\vec{b})$ is the point charge correction to the Coulomb phase-shift function, which is equal to $2 n \ln \left(\frac{b}{2 a}\right)$, a is equal to $\frac{1}{2 k b}, n=Z_{\pi} Z_{B} e^{2} / \hbar v$ is the usual Coulomb parameter and $\chi_{C}^{E}(\vec{b})$ is the extended charge correction to the Coulomb phase shift function. $\chi_{n}(\vec{b})$ is the nuclear interaction phase-shift function.
From eqs. (1) and (2), we find

$$
\begin{equation*}
F_{\pi B}(q)=\Theta(\vec{q})\left[f_{C}^{p t .}(q)+i \int_{0}^{\infty}(k b)^{2 i n+1}\left\{1-\exp \left(i \chi_{C}^{E}(\vec{b})+i \chi_{n}(\vec{b})\right)\right\} J_{o}(q b) d b\right] \tag{3}
\end{equation*}
$$

In eqs. (1) and (3), the center-of-mass correlation is treated as a global correction (denoted by $\Theta(\vec{q})$ ) multiplied by the scattering amplitude. Because of $\Theta(\vec{q})$ has an exponential form of $q^{2}$ [48], this leads to unphysical divergence as $q$ goes to high values. The large $q$-divergence is removed by incorporating the center-of-mass correlation function $\Theta(\vec{q})$ in the first order calculations [45] or in the fourth order evaluations [47] or in the full series calculations [56], of the Glauber amplitude. Such consistent treatment in the later case [56] has
modified the phase-shift functions to new forms, which are simply expressed in terms of the uncorrelated ones.

Thus, eqs. (1) and (3) become

$$
\begin{equation*}
F_{\pi B}(\vec{q})=\frac{i k}{2 \pi} \int d \vec{b} \exp (i \vec{q} \cdot \vec{b})\left\{1-\exp \left(i \bar{\chi}_{\pi B}(\vec{b})\right)\right\} \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
F_{\pi B}(q)=f_{C}^{p t .}(q)+i \int_{0}^{\infty}(k b)^{2 i n+1}\left\{1-\exp \left(i \bar{\chi}_{C}^{E}(\vec{b})+i \bar{\chi}_{n}(\vec{b})\right)\right\} J_{o}(q b) d b \tag{5}
\end{equation*}
$$

where $\bar{\chi}_{C}^{E}(\vec{b})$ is the modified extended charge correction to the Coulomb phase shift function. $\bar{\chi}_{n}(\vec{b})$ is the modified nuclear interaction phase-shift function. (The bars are introduced to distinguish the modified quantities from their corresponding uncorrelated ones).

Assuming the target ground state wave function has the form:

$$
\begin{equation*}
\Psi_{B}\left(\left\{\vec{r}_{j}\right\}\right)=\xi_{B}\left(\vec{R}_{B}\right) \Phi_{B}\left(\left\{\left\{_{j}^{\text {int }}\right\}\right), \vec{r}_{j}^{\text {int }}=\vec{r}_{j}-\vec{R}_{B},\right. \tag{6}
\end{equation*}
$$

where $\xi_{B}\left(\vec{R}_{B}\right)$ and $\Phi_{B}\left(\left\{\vec{r}_{j}^{\text {int }}\right\}\right)$ are the wave functions describing the center-of-mass motion and the internal motion of the target nucleons, respectively.

Accordingly, the modified optical phase-shift function, $\bar{\chi}_{n}(\vec{b})$, can be written in terms of the uncorrelated phase-shift function, $\bar{\chi}_{n}(\vec{b})$, as [47]
$\exp \left[i \bar{\chi}_{n}(\vec{b})\right]=\int_{0}^{\infty} J_{o}(q b) \Theta(q) q d q \int_{0}^{\infty} J_{o}\left(q b^{\prime}\right) \exp \left[i \bar{\chi}_{n}\left(\vec{b}^{\prime}\right)\right] b^{\prime} d b^{\prime}$,
where

$$
\begin{equation*}
\Theta(q)=\left[<\xi_{B}\left(\vec{R}_{B}\right)\left|e^{-i \vec{q} \cdot \vec{R}_{B}}\right| \xi_{B}\left(\vec{R}_{B}\right)>\right]^{-1} \tag{8}
\end{equation*}
$$

and

$$
\begin{equation*}
\exp \left[i \bar{\chi}_{n}(\vec{b})\right]=<\Psi_{B}\left(\left\{\vec{r}_{j}^{\prime}\right\}\right)\left|\exp \left[i \chi_{n}\left(\vec{b},\left\{\vec{s}_{j}^{\prime}\right\}\right)\right]\right| \Psi_{B}\left(\left\{\vec{r}_{j}^{\prime}\right\}\right)> \tag{9}
\end{equation*}
$$

$\left\{\vec{s}_{j}^{\prime}\right\}$ are the projections of the position vectors $\left\{\vec{r}_{j}^{\prime}\right\}$ of the target nucleons on the impact parameter plane. With the definition of the profile function

$$
\begin{equation*}
\Gamma_{n}(\vec{b})=1-\exp \left[i \bar{\chi}_{n}(\vec{b})\right] \tag{10}
\end{equation*}
$$

the phase-shift function is given by

$$
\begin{equation*}
\exp \left[i \bar{\chi}_{n}\left(\vec{b}, \vec{s}_{1}^{\prime}, \vec{s}_{2}^{\prime}, \ldots, \vec{s}_{B}^{\prime}\right)\right]=\prod_{j=1}^{B}\left[1-\Gamma_{j}\left(\vec{b}-\vec{s}^{\prime}\right)\right] \tag{11}
\end{equation*}
$$

where $\Gamma_{j}$ represents the profile function of scattering between the pion and the jth nucleon in the target nucleus $B$. It is related to the pion-nucleon $(\pi N)$ elastic scattering amplitude $f_{j}$ by

$$
\begin{equation*}
\Gamma_{j}(\vec{b})=\frac{1}{2 \pi i k_{\pi}} \int d^{2} q e^{-(i \vec{q} \cdot \vec{b})} f_{j}(\vec{q}) \tag{12}
\end{equation*}
$$

where $k_{\pi}$ is the wave number of the incident pion.
Assuming for simplicity that all the $\pi N$ amplitudes are equal (which is approximately true at high energy) and neglecting further spin effects, $f_{j}$ can be parameterized by [56]

$$
\begin{equation*}
f_{j}(\vec{q})=\frac{k_{\pi} \sigma}{4 \pi}(i+\rho) e^{-a q^{2} / 2} \tag{13}
\end{equation*}
$$

Here, $\sigma$ is the total $\pi N$ cross-section, $\rho$ is the ratio of the real to the imaginary parts of the forward $\pi N$ scattering amplitude and "a" is taken to be complex; the real part is typically the slope parameter $\left(\beta^{2}\right)$ of the $\pi N$ elastic scattering differential cross section while the imaginary part is a free parameter introducing a phase variation of the $\pi N$ scattering amplitude, which is taken here to be zero.

Inserting eq. (13) into eq. (12), we obtain

$$
\begin{equation*}
\Gamma_{j}\left(\vec{b}-\vec{s}_{j}^{\prime}\right)=g \exp \left[-\left(\vec{b}-\vec{s}_{j}^{\prime}\right)^{2} / 2 a\right] \tag{14}
\end{equation*}
$$

with

$$
g=\frac{\sigma}{4 \pi a}(1-i \rho)
$$

To perform the integrations (8) and (9) analytically, consider the approximation in which the nucleons inside the target nucleus are completely uncorrelated, then we can write

$$
\begin{equation*}
\left|\Psi_{B}\right|^{2}=\prod_{j=1}^{B} \rho_{B}\left(\vec{e}_{j}^{\prime}\right) \tag{15}
\end{equation*}
$$

where $\rho_{B}$ is assumed to be of single-Gaussian type like,

$$
\begin{equation*}
\rho_{B}(\vec{r})=\left[\frac{\alpha_{B}^{2}}{\pi}\right]^{3 / 2} \exp \left(-\alpha_{B}^{2} r^{2}\right) \tag{16}
\end{equation*}
$$

where " $\alpha_{B}$ " is related to the rms radius by

$$
\alpha_{B}=\sqrt{3 / 2}\left[\frac{1}{\left\langle r_{B}^{2}>^{1 / 2}\right.}\right]
$$

Adopting the wave function (15) with the density (16) and using the same analysis as that utilized in our references [55, 56] with the invoking of the description mentioned above, eq. (8) for $\Theta(q)$ yield [48]

$$
\begin{equation*}
\Theta(q)=\exp \left[\frac{q^{2}}{4} \frac{1}{B \alpha_{B}^{2}}\right] \tag{17}
\end{equation*}
$$

and eq. (9) after integrating over the variables x and y using the same procedures as that given in Ref. [57] with the canceling out one of the Gaussians, gives the analytic result

$$
\begin{equation*}
\exp \left[i \chi_{n}\right]=1+\sum_{\mu}^{B} \sum_{\lambda_{m} u} T\left(\mu, \lambda_{\mu}\right) \prod_{j=1}^{B}\left\{Z_{o}\right\}^{\Delta_{1 j}\left(\mu, \lambda_{\mu}\right)} \tag{18}
\end{equation*}
$$

where $Z_{o}$, has the form

$$
Z_{o}=-g C_{B} R_{o} \times \exp \left(-W_{o} b^{2}\right)
$$

with

$$
\begin{aligned}
C_{B} & =\alpha_{B}^{2} / \pi \\
R_{o} & =4 a^{2} T_{1} \times \frac{\pi^{2}}{a_{11}(j, 1)}, \quad W_{o}=a_{o}(j)-\frac{C_{1}^{2}(j, 1)}{4 a_{11}(j, 1)} \\
T_{1} & =\frac{1}{2 a^{2}\left(2 a^{2} \alpha_{B}^{2}+R u(1,1)\right)}, \quad a_{o}(j)=\alpha_{B}^{2} \\
a_{11}(j, 1) & =\alpha_{B}^{2}+\frac{1}{2 a^{2}} \operatorname{sg}(1,1)-T_{1}, \quad g=\frac{\sigma}{4 \pi a}(1-i \rho) \quad \text { and } C_{1}(j, 1)=2 \alpha_{B}^{2},
\end{aligned}
$$

where, the indices $\left(\mu, \lambda_{\mu}\right)$ characterize an orbit with an order of scattering $\mu$ and serial index $\lambda_{\mu} . R_{o}, W_{o}, a_{o}(j), a_{11}(j, 1)$ and $C_{1}(j, 1)$ are independent on $j$, i.e., they are the same for all $j$. Obviously, Eq. (18) has an advantage in reducing the computer CPU time spent in the calculations by restoring $Z_{o}$ at $\Delta_{1 j}=0,1$.

In the method of Yin et al.[49], each orbit $\left(\mu, \lambda_{\mu}\right)$ is represented by a matrix $\Delta\left(\mu, \lambda_{\mu}\right)$ with element $\Delta_{1 j}\left(\mu, \lambda_{\mu}\right)$ either equal to " 1 " or " 0 ". This matrix $\Delta\left(\mu, \lambda_{\mu}\right)$ corresponds to one typical term expressing the multi-cluster elementary collision and its element is equal to " 1 " if $\Gamma_{1 j}$ appears in the expansion term and is equal to " 0 " if it is absent. $T\left(\mu, \lambda_{\mu}\right)$ is the number of repetitions (length) of the orbit ( $\mu, \lambda_{\mu}$ ), which is determined by using the properties of the permutation group $G_{1}=S_{1} \otimes S_{B}$.

Here, "Ru" and "sg" are the row and column sum vectors of the corresponding orbit, respectively.

Eq. (18) is developed by taking the one-particle system as our cluster particle and hence, $N_{1}=B$ (i.e., $\mu_{1}: 1 \rightarrow B$ ), $N_{2}=1$ (i.e., $\mu_{2}=1$ ), $M_{A}=M_{N}=1, M_{B}=B$.

Incorporating the c.m. correlation, the modified phase-shift function, $\bar{\chi}_{n}(\vec{b})$ can be expressed as

$$
\begin{equation*}
\exp \left[i \bar{\chi}_{n}(\vec{b})\right]=1+\sum_{\mu}^{B} \sum_{\lambda_{\mu}} T\left(\mu, \lambda_{\mu}\right) \prod_{j=1}^{B}\left\{\bar{Z}_{o}\right\}^{\Delta_{1}\left(\mu, \lambda_{\mu}\right)} \tag{19}
\end{equation*}
$$

The form of $\bar{Z}_{o}$ is obtained by inserting the expressions of $Z_{o}$ and $\Theta(q)$ into Eq. (7), yielding

$$
\begin{equation*}
\bar{Z}_{o}=-g C_{B} \bar{R}_{o} \times \exp \left(-\bar{W}_{o} b^{2}\right) \tag{20}
\end{equation*}
$$

with

$$
\bar{W}_{o}=\left[\frac{1}{W_{o}}-\frac{1}{B \alpha_{B}^{2}}\right]^{-1} \quad \text { and } \quad \bar{R}_{o}=\frac{R_{o} \times \bar{W}_{o}}{W_{o}}
$$

Finally, the modified extended charge correction to the Coulomb phase-shift, $\bar{\chi}_{C}^{E}(\vec{b})$, has already been derived analytically in Ref. [47] for a single-Gaussian density where it was found to have the form

$$
\begin{equation*}
\bar{\chi}_{C}^{E}(\vec{b})=n E_{1}\left(b^{2} / \bar{R}_{B}^{2}\right), \tag{21}
\end{equation*}
$$

where $E_{1}(z)$ is the exponential integral function and,

$$
\bar{R}_{B}^{2}=R_{B}^{2}\left(1-B^{-1}\right) ; \quad R_{B}^{2}=\frac{1}{\alpha_{B}^{2}}
$$

With the results of eqs. (19), (20) and (21), the scattering amplitude $F_{\pi B}(q)$ can be obtained by performing the integration in Eq. (5) numerically. The angular distribution of the elastic scattering is given by

$$
\begin{equation*}
\frac{d \sigma(\bar{q})}{d \Omega}=\left|F_{\pi B}(\bar{q})\right|^{2} \tag{22}
\end{equation*}
$$

The total elastic cross section, $\sigma_{e l}$, is given by subtracting the total reaction cross section " $\sigma_{R}$ " from the total cross section which is related to the forward scattering amplitude of the elastic scattering by the optical theorem as:

$$
\begin{equation*}
\sigma_{t o t}=\frac{4 \pi}{k} \operatorname{Im} F_{\pi B}(q=0) \tag{23}
\end{equation*}
$$

The reaction cross section is found to has the form [47, 70, 71]

$$
\begin{gather*}
\sigma_{R}=2 \pi \int_{0}^{\infty}\left(1-\left|e^{i \bar{\chi}_{n}(\vec{b})}\right|^{2}\right) b d b  \tag{24}\\
\sigma_{e l}=\sigma_{t o t}-\sigma_{R} \tag{25}
\end{gather*}
$$

With the results of Eqs. (23) and (24), the total elastic cross section, $\sigma_{e l}$, can be easily obtained from Eq. (25).

## III. RESULTS AND DISCUSSION

In the framework of the formalisms presented in the above section, we have calculated the differential cross section for a set of elastic nuclear reactions; namely, $\pi^{-}-{ }_{2} \mathrm{He}^{4}$ at incident energy $180 \mathrm{MeV}, \pi^{ \pm}-{ }_{3} \mathrm{Li}^{6}$ at $240 \mathrm{MeV}, \pi^{-}-{ }_{6} \mathrm{C}^{12}$ at incident energies 180,200 and $260 \mathrm{MeV}, \pi^{+}-{ }_{8} \mathrm{O}^{16}$ at 240 and 270 MeV and $\pi^{ \pm}-{ }_{20} \mathrm{Ca}^{40}$ at energy 292.5 MeV . Also, we have calculated the total cross section for the elastic collisions, namely; $\pi^{+}-{ }_{3} \mathrm{Li}^{6}$ at incident energy 128 and 259 MeV , $\pi^{+}-{ }_{6} \mathrm{C}^{12}$ at $89 \mathrm{MeV}, \pi^{+}-{ }_{20} \mathrm{Ca}^{40}$ at $292.5 \mathrm{MeV}, \pi^{-}-{ }_{3} \mathrm{Li}^{6}$ at incident energy 115,156 and $259 \mathrm{MeV}, \pi^{-}-{ }_{6} \mathrm{C}^{12}$ at incident energy $115,120,259,260$ and 289 MeV and $\pi^{-}-{ }_{20} \mathrm{Ca}^{40}$ at 292.5 MeV . The total elastic cross section is evaluated for the elastic scattering of $\pi^{-}$with ${ }_{6} \mathrm{C}^{12}$ at incident energies 180 , 200, 230, 260 and 280. The theoretical results were compared with the available experimental data. The ingredients needed to perform these calculations are the parameters associated with the $\pi N$ scattering amplitude and the nuclear densities as well as the orbits, lengths and $\Delta$-matrices of the groups

$G_{1}=S_{1} \otimes S_{B}$ and $G_{2}=S_{1} \otimes S_{1}$. For the above energies, we used the values of the $\pi N$ parameters given in Table (1).

The values of the rms radii we have used for the present nuclei are given in Table (2).

The structure specific to the considered reactions and the corresponding orbits, lengths and $\Delta$-matrices are exhibited in the appendix. The center-of-mass correlation is treated here in a consistent way in which its expressing function $(\Theta(q))$ is incorporated in each order of the optical phase-shift expansion. Such function is found to have an exact form in the case of the employed single-Gaussian density [48]. To show to what extent the inclusion in-medium $\pi N$ scattering amplitude affects the angular distribution, we first evaluate it with the free $\pi N$ parameters $\left(\sigma_{\text {free }}, \sigma_{\text {free }}\right)$. Second, we calculate it with the effective $\pi N$ ones ( $\sigma_{e f f .}$, $\sigma_{e f f .}$ ). The results obtained from these calculations for the considered reactions are shown in Figs. (1-10) as dashed and solid curves, respectively. Fig. 1 contains the results obtained for $\pi^{-}-{ }_{2} \mathrm{He}^{4}$ at 180 MeV . We see from this figure that the predicted angular distribution obtained with the effective $\pi N$ parameters (referred to as solid curve) is much better than that obtained using the free $\pi N$ ones (referred to as dashed curve). For $\pi^{ \pm}-{ }_{3} \mathrm{Li}^{6}$ reaction, the results obtained, Figs. 2, 3, show that except around the minima, the angular distributions calculated with $\left(\sigma_{e f f .}, \sigma_{e f f .}\right)$ are better in comparison with that evaluated with $\left(\sigma_{\text {free }}, \sigma_{\text {free }}\right)$ ones. In particular, the dashed curves reproduced well the positions of the minima while the solid curves reproduce more satisfactorily the backward angles in comparison with the results shown by the dashed curves. For $\pi^{-}-{ }_{6} \mathrm{C}^{12}$ case, Figs. 4-6, it is shown that the inclusion of the in-medium effect is more comprehensive in fitting the corresponding experimental data, especially at large angles than that neglecting it. Enlarging the mass of the target nucleus as in the $\pi^{+}-{ }_{8} \mathrm{O}^{16}$ reaction, Figs. 7, 8, the improvement shown here in these figures by the solid curves in comparison with the dashed curves reflects the proper account for the full Glauber series calculation in

FIG. 1: Plots the differential cross section, $(d \sigma / d \Omega)$, versus scattering angle for the elastic scattering of $\pi^{-}$with ${ }_{2} \mathrm{He}^{4}$ at incident energy 180 MeV . The solid curve represents the full series calculations with the in-medium $\pi N$ amplitude, the dashed curve represents the full series calculations with free $\pi N$ amplitude, the dotted curve represents the first order calculations with free $\pi N$ amplitude. The dots are the experimental data.

FIG. 2: The same as Fig. 1 but for $\pi^{+}$with ${ }_{3} \mathrm{Li}^{6}$ at incident energy 240 MeV .
addition to the inclusion of the in-medium $\pi N$ scattering amplitude. For $\pi^{ \pm}-{ }_{20} \mathrm{Ca}^{40}$ reaction, Figs. 9, 10, one can easily see that the in-medium calculations of the angular distributions are still better than that using the free parameters. As we referred before $[58,59]$ that the use of density distribution more suitable than that employed in our calculations may improve our results. This will be the subject of future work.

To ensure the necessity of accounting for the full multiple scattering series of the Glauber amplitude, comparison has been made with the similar first-order calculations (optical limit result) using Franco and Varma approach [47]. The details of their analysis and the phase-shift expressions developed are quoted in their reference. Figs. (1-10) contain the results of such comparison where the first order calculations are referred to as the dotted curves while the full series evaluations are referred to as the dashed curves. An overall picture of these figures shows that the full series results are relatively better than the optical limit results, especially at large angles. This may ensure the necessity of including the higher order

TABLE III: A comparison of the total cross-section $\left(\sigma_{T}\right)$ results from this work and the corresponding experimental data, for the elastic scattering of $\pi^{+}$with some of the considered stable nuclei at different energies.

| Nucleus | Energy (MeV) | $\sigma_{T}(\mathrm{mb})$ |  | Exp. Data [Ref.] |
| :---: | :---: | :---: | :---: | :---: |

TABLE V: A comparison of the elastic cross-section ( $\sigma_{e l}$ ) results from this work and the corresponding experimental data, for the elastic scattering of $\pi^{-}$with ${ }_{6} \mathrm{C}^{12}$ at different energies.

|  | $\sigma_{T}(\mathrm{mb})$ |  |  |
| :--- | :--- | :--- | :--- |
| Energy (MeV) | Full series <br> with $\sigma_{\text {free }}$OLA <br> with $\sigma_{\text {free }}$ |  | Exp. Data [Ref.] |
| 180 | 245.24 | 235.57 | $247 \pm 11[29]$ |
| 200 | 233.78 | 224.39 | $241 \pm 11[29]$ |
| 230 | 221.88 | 211.46 | $225 \pm 17[29]$ |
| 260 | 198.54 | 187.34 | $212 \pm 18[29]$ |
| 280 | 185.10 | 173.82 | $199 \pm 18[29]$ |

terms at large momentum transfers.
As an additional check, we have calculated the total cross section $\left(\sigma_{t o t}\right)$ for the elastic scattering of $\pi^{+}$and/or $\pi^{-}$with ${ }_{3} \mathrm{Li}^{6},{ }_{6} \mathrm{C}^{12}$ and ${ }_{20} \mathrm{Ca}^{40}$, and total elastic cross section $\left(\sigma_{e l}\right)$ for $\pi^{-}-{ }_{6} \mathrm{C}^{12}$ at different incident energies. The results of the calculated total and total elastic cross-sections and the corresponding experimental data are listed in Tables (3-5). One can easily see from these tables that the full series calculations for the total and total elastic cross-sections are much better than that calculated by the optical limit approach. This ensures the necessity of including the full multiple scattering series of the Glauber amplitude.

## IV. CONCLUSION

In the framework of Glauber's multiple scattering theory and taking into account the Coulomb contribution and a consistent treatment of the center-of-mass (c.m.) correlation, we

FIG. 3: The same as Fig. (1) but for $\pi^{-}$with ${ }_{3} \mathrm{Li}^{6}$ at incident energy 240 MeV .
have investigated the elastic scattering of positive and /or negative pions by nuclei, like, ${ }_{2} \mathrm{He}^{4},{ }_{3} \mathrm{Li}^{6},{ }_{6} \mathrm{C}^{12},{ }_{8} \mathrm{O}^{16}$, and ${ }_{20} \mathrm{Ca}^{40}$ at intermediate energies. We have calculated the differential, total and total elastic cross sections for the considered reactions. These calculations are carried out by considering the followings; (i) The full series expansion of the Glauber amplitude with free $\pi N$ parameters ( $\sigma_{\text {free }}, \sigma_{\text {free }}$ ), (ii) The first order correction of the Glauber amplitude (OLA) with free $\pi N$ parameters $\left(\sigma_{\text {free }}, \sigma_{\text {free }}\right)$, (iii) The full series expansion of the Glauber amplitude with the in-medium $\pi N$ parameters ( $\sigma_{e f f .}$, $\sigma_{e f f .}$.). We compared our results with the corresponding experimental data. It is shown that, except around the minima, the full series results of the differential cross-sections employing the in-medium $\pi N$ amplitude are more comprehensive in

FIG. 4: The same as Fig. (1) but for $\pi^{-}$with ${ }_{6} \mathrm{C}^{12}$ at incident energy 180 MeV .

FIG. 5: The same as Fig. (1) but for $\pi^{-}$with ${ }_{6} \mathrm{C}^{12}$ at incident energy 200 MeV .
describing the scattering data rather than that using the free $\pi N$ one. Also, one can easily see that the full series calculations of the Glauber amplitude are relatively better than the optical limit result (OLA), especially at backward angles.

An overall view of the results shown before, we emphasize that the full series expansion of the Glauber amplitude

FIG. 6: The same as Fig. (1) but for $\pi^{-}$with ${ }_{6} \mathrm{C}^{12}$ at incident energy 260 MeV .

FIG. 7: The same as Fig. (1) but for $\pi^{+}$with ${ }_{8} \mathrm{O}^{16}$ at incident energy 240 MeV .

FIG. 8: The same as Fig. (1) but for $\pi^{+}$with ${ }_{8} \mathrm{O}^{16}$ at incident energy 270 MeV .
is not sufficient to bring the Glauber theory closer to the experimental data. It must consider some corrections like; inmedium $\pi N$ amplitude, phase-variation parameter of the $\pi N$ scattering amplitude which has its strongest effect around the diffraction patterns, more realistic density distribution like harmonic-oscillator density. The last two corrections will be

FIG. 9: The same as Fig. (1) but for $\pi^{+}$with ${ }_{20} \mathrm{Ca}^{40}$ at incident energy 292.5 MeV .

FIG. 10: The same as Fig. (1) but for $\pi^{-}$with ${ }_{20} \mathrm{Ca}^{40}$ at incident energy 292.5 MeV .
done in our future work.

## V. APPENDIX

This appendix contains tables in which we present the orbits, lengths and - matrices employed in our calculations. We obtained them by enumerating and investigating all possible combinations of collisions according to their permutation using the method introduced in Ref. [49]. In the present work, the elastic collisions, $\pi^{-}-{ }_{2} \mathrm{He}^{4}, \pi^{ \pm}-{ }_{3} \mathrm{Li}^{6}, \pi^{-}-{ }_{6} \mathrm{C}^{12}$, $\pi^{+}-{ }_{8} \mathrm{O}^{16}$ and $\pi^{ \pm}-{ }_{20} \mathrm{Ca}^{40}$ have been studied. Each reaction according to its assumed cluster structure needs the orbits, lengths and $\Delta$-matrices of the groups $G_{1}=S_{1} \otimes S_{B}$ and $G_{2}=S_{1} \otimes S_{1}$ (defined in chapter II). For the sake of brevity, we give only the tables of the non-similar groups.

Total number of orbits (including the orbits not shown $)=4$.
Total number of orbits (including the orbits not shown) $=6$.
Total number of orbits (including the orbits not shown) $=12$.

Total number of orbits (including the orbits not shown) $=16$.

Total number of orbits (including the orbits not shown) $=40$.

Total number of orbits (including the orbits not shown $)=1$.
In these tables, the first column represents the order of multiple scattering which ranges from 1 to $1 \times n$ while $\lambda_{\mu}$ in the second column represents the serial index used to number the
orbits of order $\mu$. The third column represents the length of the orbit $T\left(\mu, \lambda_{\mu}\right)$. In the fourth column the $1 \times n$-digit binary numbers give the $\Delta$-matrices of the group $G=S_{1} \otimes S_{n}$. The $n$-digits are the elements $\Delta_{1 i}, i=1,2, \ldots, n$.

Table 1. Orbits, lengths and $\Delta$-matrices for $G_{1}=S_{1} \otimes S_{4}$.

| $\mu$ | $\lambda_{\mu}$ | $T\left(\mu, \lambda_{\mu}\right)$ | $\Delta\left(\mu, \lambda_{\mu}\right)$ |
| :---: | :---: | :---: | :---: |
| 1 | 1 | 4 | 1000 |
| 2 | 1 | 6 | 1100 |

By symmetry, the orbits, lengths and $\Delta$-matrices for $\mu$ 's which are not shown in our tables could be easily deduced

Table 2. Orbits, lengths and $\Delta$-matrices for $G_{1}=S_{1} \otimes S_{6}$.

| $\mu$ | $\lambda_{\mu}$ | $T\left(\mu, \lambda_{\mu}\right)$ | $\Delta\left(\mu, \lambda_{\mu}\right)$ |
| :---: | :---: | :---: | :---: |
| 1 | 1 | 6 | 100000 |
| 2 | 1 | 15 | 110000 |
| 3 | 1 | 20 | 111000 |

Table 3. Orbits, lengths and $\Delta$-matrices for $G_{1}=S_{1} \otimes S_{12}$.

| $\mu$ | $\lambda_{\mu}$ | $T\left(\mu, \lambda_{\mu}\right)$ | $\Delta\left(\mu, \lambda_{\mu}\right)$ |
| :---: | :---: | :--- | :--- |
| 1 | 1 | 12 | 100000000000 |
| 2 | 1 | 66 | 110000000000 |
| 3 | 1 | 220 | 111000000000 |
| 4 | 1 | 495 | 111100000000 |
| 5 | 1 | 792 | 111110000000 |
| 6 | 1 | 924 | 111111000000 |

from the Tables. This is carried out by using the results for order $\mu^{\prime}=m \times n-\mu$ and interchanging the 0 's and 1 's of $\Delta\left(\mu^{\prime}, \lambda_{\mu^{\prime}}\right)$. The indices $\lambda_{\mu}$ and $\lambda_{\mu^{\prime}}$ are the same and the lengths $T\left(\mu, \lambda_{\mu}\right)$ and $T\left(\mu^{\prime}, \lambda_{\mu^{\prime}}\right)$ are equal. The matrix $\Delta(n, 1)$ has elements $\Delta_{1 j}$ equal to 1 .

Table 4. Orbits, lengths and $\Delta$-matrices for $G_{1}=S_{1} \otimes S_{16}$.

| $\mu$ | $\lambda_{\mu}$ | $T\left(\mu, \lambda_{\mu}\right)$ | $\Delta\left(\mu, \lambda_{\mu}\right)$ |
| :---: | :--- | :--- | :--- |
| 1 | 1 | 16 | 1000000000000000 |
| 2 | 1 | 120 | 1100000000000000 |
